# Kansas' Forest Resources in 2004

The North Central Research Station's Forest Inventory and Analysis (NCFIA) program began fieldwork for the fifth forest inventory of Kansas' forest resources in 2001. This inventory initiated the new annual inventory system in which one-fifth of the field plots (considered one panel) in the State are measured each year. A complete inventory consists of measuring, compiling, and reporting the data for all plots in all five panels. Once the plots in all panels have been measured, each will be remeasured approximately every 5 years. For example, the field plots measured in 2003 will be remeasured in 2008.

In 2004, NCFIA continued the annual inventory effort with the fourth panel of the fifth Kansas forest inventory. Previous inventories of Kansas are dated 1936, 1965, 1981, and 1994 (Kansas State College 1939, Chase and Strickler 1968, Spencer *et al.* 1984, Raile and Spencer 1984, Leatherberry *et al.* 1999). This fifth inventory of Kansas' forest resources will be completed in 2005. However, because each year is a systematic sample of the State's forest and timely information is needed about Kansas' forest resources, estimates have been prepared from data gathered during the first 4 years of the inventory. Measurements from four panels, approximately 80 percent of the field plots of the complete inventory, are the basis for the estimates presented in this report. The underlying data are a combination of measurements for the first year's panel in 2001, the second year's panel in 2002, the third year's panel in 2003, and the fourth year's panel in 2004. The results presented are estimates based on sampling techniques; estimates for this report were compiled assuming the 2001, 2002, 2003, and 2004 data represent one sample. As additional annual panels are completed, the precision of the estimates will increase and additional data will be released.

Estimates from new inventories are often compared with estimates from earlier inventories to determine trends in forest resources. However, for the comparisons to be valid, the procedures used in the two inventories must be similar. As a result of our ongoing efforts to improve the efficiency and reliability of the inventory, several changes in procedures and definitions have been made since the last Kansas inventory in 1994 (Leatherberry *et al.* 1999). Although these changes will have some impact on statewide estimates of forest area, timber volume, and tree biomass, they may have significant impacts on plot classification variables such as forest type and stand-size class. Some of these changes make it inappropriate to directly compare portions of the 2001-2004 estimates with those published for earlier inventories. Except for oak/hickory, forest type descriptions in this report are categorized by broad groups and species not necessarily found in Kansas. Forest type subcategories more accurately describe the forests of the State. These subcategories include elm/ash/locust for maple/beech/birch, eastern redcedar/hardwood for oak/pine, and eastern redcedar for pinyon/juniper.

## About the Authors:

**W. Keith Moser, Mark H. Hansen, and Gary J. Brand** are Research Foresters with the North Central Research Station, St. Paul, MN.

**Melissa Powers** is a Forest Resource Specialist with the Kansas Forest Service, Manhattan, KS.

## RESULTS

### Area

Forest land area was 2.13 million acres in 2004 (table 1). Five percent of forest land in Kansas is owned by public agencies and 94.7 percent is owned by private landowners. More than 5.5 percent of forest land area is dominated by conifers, and 93.4 percent is dominated by hardwoods, and the remainder is classified as nonstocked<sup>1</sup>. Oak/hickory forests constitute 56 percent of the total hardwood area. The

<sup>1</sup>Nonstocked land is timberland less than 10 percent stocked with all live trees.

pinyon/juniper forest group (primarily eastern redcedar)<sup>2</sup> constituted 89.1 percent of all forest land dominated by conifers.

Forest land is defined as land 1 acre in size, 120 feet in width, and possessing 10 percent stocking of live trees. It has three components:

1. Timberland<sup>3</sup>—forest land not restricted from harvesting by statute, administrative regulation, or designation and capable of growing trees at a rate of 20 cubic feet per acre per year
2. Reserved forest land—land restricted from harvesting by statute, administrative regulation, or designation (e.g., national parks and lakeshores, Federal wilderness areas)
3. Other forest land—land not capable of growing trees at a rate of 20 cubic feet per acre per year and not restricted from harvesting

<sup>2</sup>In inventories before 1999, eastern redcedar was distinguished from pinyon/juniper.

<sup>3</sup>Timberland may not be equivalent to the area actually available for commercial timber harvesting or other access. The actual availability of land for various uses depends upon owner decisions that consider economic, environmental, and social factors.

Timberland area, 2.05 million acres, has continued to increase since its low point in the 1936 inventory (fig. 1). The significant jump in forest land and timberland area since the last periodic inventory is due to many factors, including the conversion of croplands and pastures to forest, the growth of trees on poorly stocked lands, and a definitional change. Previously, most of the forest lands that were grazed or that provided shelter from the wind were not classified as forest land. Since 2001, such lands have been classified as forest land if they meet the forest land definition.

The hardwood forest types dominate the timberland area (table 2), particularly the oak/hickory group (table 3, fig. 2). Hardwoods made up 93.4 percent of the total acreage, 88.3 percent of all public land acreage, and 93.7 percent of all private landholdings. Most forest type groups, except for the pinyon/juniper (eastern redcedar) group, are in the sawtimber or poletimber stand-size classes.

Figure 3 shows the area of timberland by stand-size class over the years. The areas in poletimber and sawtimber classes have steadily increased since the 1965 inventory.

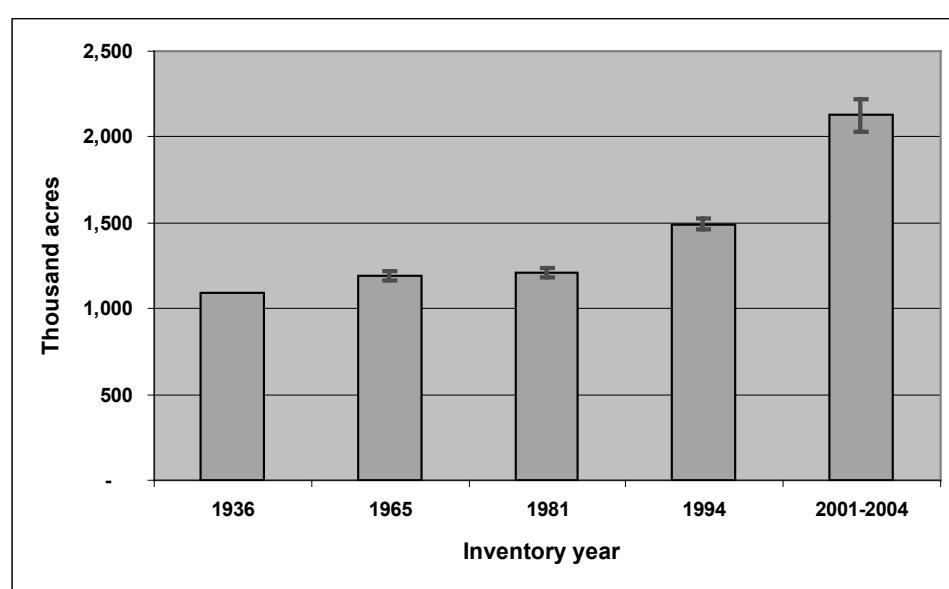

Figure 1.—Area of timberland, Kansas, 1936-2004. (Note: The sampling error associated with an inventory estimate is represented by the vertical line at the top of its bar. No sampling error was available for the 1936 survey; timberland area was calculated using the total forest land area for 1936 multiplied by a ratio of timberland to total forest land from 1965.)

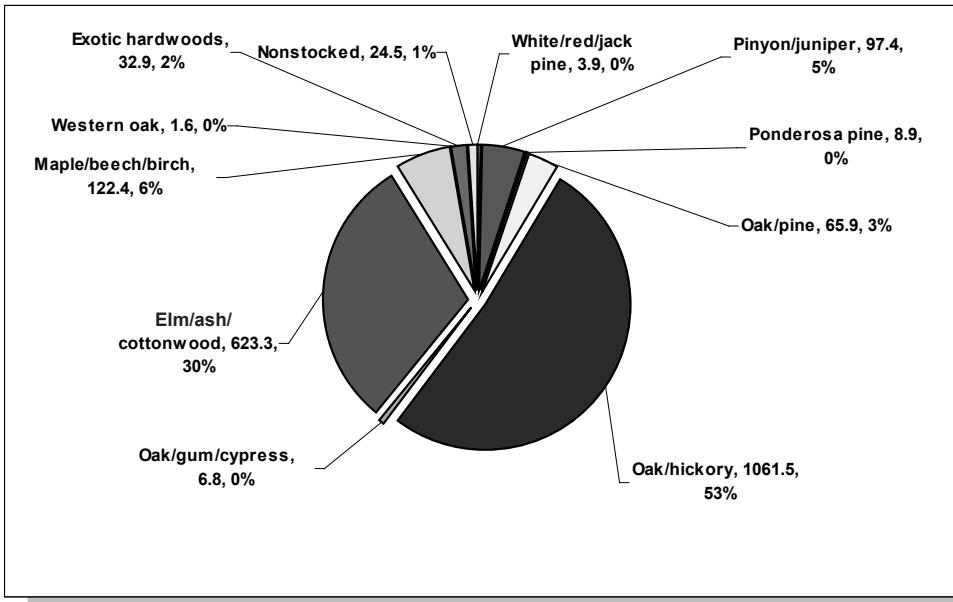

Figure 2. — Area of timberland by forest type group<sup>1</sup>, in thousands of acres, for Kansas, 2001-2004.

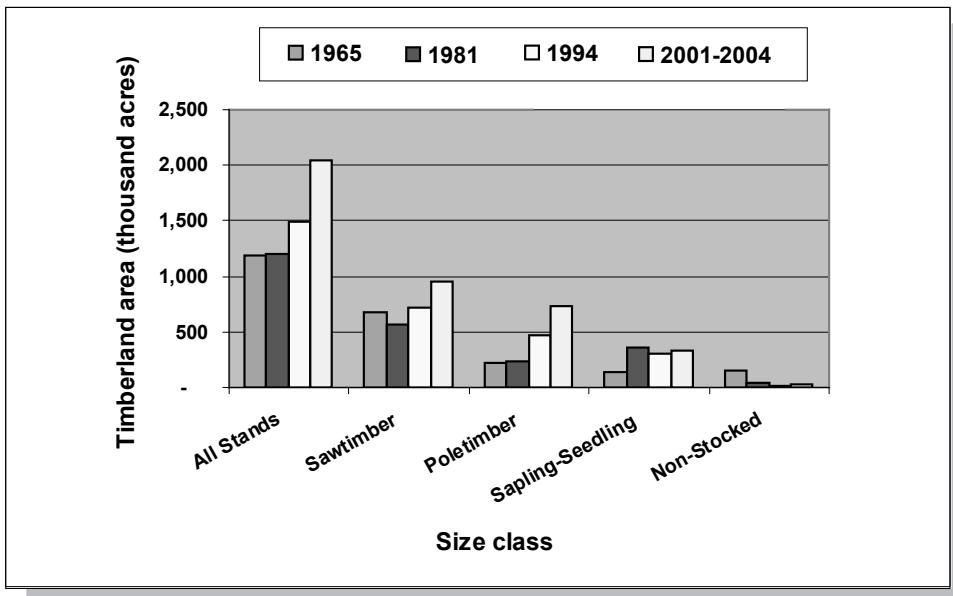

Figure 3. — Area of timberland by stand-size class, Kansas, 1965-2004<sup>2</sup>.

<sup>1</sup>Under Forest Inventory and Analysis classifications, forest type groups are composed of several, sometimes related, forest types. For example, the oak/pine forest type group consists of the eastern redcedar/hardwood and shortleaf pine forest types. In tables 3 and 6 and fig. 2, the maple/beech/birch forest type group in Kansas is primarily made up of elm/ash/locust; pinyon/juniper is entirely eastern redcedar; and oak/pine is mainly redcedar/hardwood.

<sup>2</sup>See footnote 2 on page 2.

## Volume

The net volume of all live trees on forest land, which includes growing stock, rough trees, and rotten trees, was 2.75 billion cubic feet (table 4). Hardwoods constituted just under 2.7 billion cubic feet, and softwoods were more than 92 million cubic feet of all live tree volume. Net volume of all oaks was 498 million cubic feet or 18.8 percent of all hardwood live tree volume. Select oaks (red and white) constituted 372 million cubic feet in volume or 74.8 percent of all oaks and 14.0 percent of all hardwood live tree volume.

On timberland, net volume of all live trees and saveable dead trees was 2.73 billion cubic feet (table 5, fig. 4). Net volume of all live trees was 2.69 billion cubic feet or 98.4 percent of total live tree volume. The difference between the total volume of all live trees on timberland and the total volume of all live trees on forest land (2.75 billion cubic feet) (table 4) represents timber on land that is either low productivity (incapable of growth greater than 20 cubic feet per acre per year at the culmination of mean annual increment) or reserved (e.g., parks, wilderness areas). Of the 1.45 billion cubic feet of growing-stock volume, 1.10 billion cubic feet or 76 percent was sawtimber volume.

Hardwoods constituted 97.2 percent of total sawtimber volume and softwoods were 2.8 percent of the total.

Cull<sup>4</sup> tree volume, at 1.2 billion cubic feet, was 46.1 percent of all live trees. The softwood cull tree volume represented 35.9 percent of the total live-tree softwood volume, whereas hardwood culls represented 46.4 percent of the total hardwood volume. The phototropic and decurrent growth habits of hardwoods and the poor stem form resulting from inadequate self-pruning, particularly in more open stands, might explain the disparity in the cull percentage. The large amount of volume growing in low-density stands, particularly those formerly classified as woody pastures, as well as the large number of noncommercial species tallied, would also explain the high total percentage of cull trees.

The net volume of growing stock on timberland totaled 1.45 billion cubic feet (table 6). Growing-stock volume has substantially increased since 1965 (fig. 5). More than 97

<sup>4</sup>Classifying a tree as cull follows strict guidelines of projected number of logs and log lengths and tree species. Local utilization standards may permit the utilization of trees classified in this inventory as "cull."

Figure 4.—Net volume on timberland, in million cubic feet, by timber class and size class, Kansas, 2001–2004.

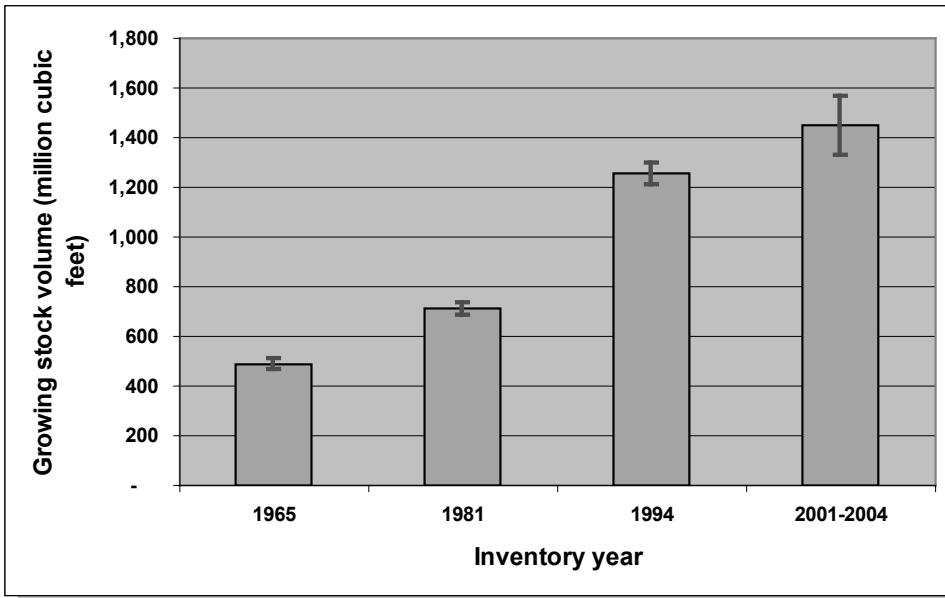

Figure 5.—Net volume of growing stock on timberland, in millions of cubic feet, for Kansas, 1965-2004.

percent of that total was in hardwood forest types, 2 percent (29.2 million cubic feet) was in conifer forest types, and the remainder was in the nonstocked category. Table 6 reports the volumes for softwoods and hardwoods for each

forest type group. For example, the oak/pine group had 14.0 million cubic feet of softwoods and 19.4 million cubic feet of hardwoods (fig. 6).

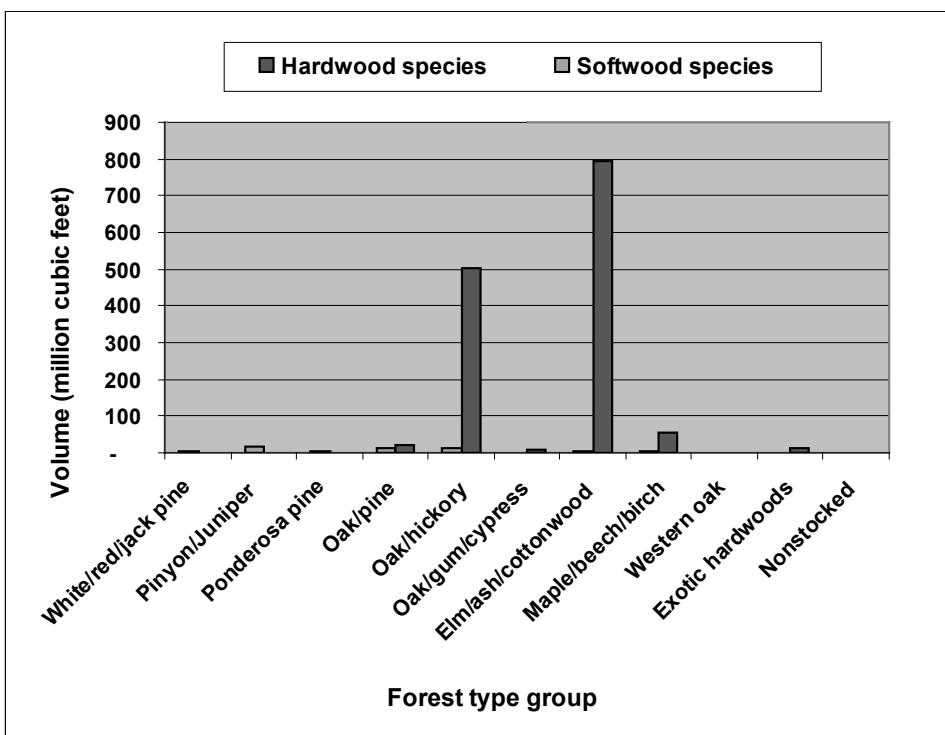

Figure 6.—Net volume of growing stock on timberland by forest type group, in millions of cubic feet, for Kansas, 2001-2004.

Table 7 shows net volume of growing stock on timberland by species group and diameter class. The totals for softwood and hardwood volumes, 57.6 million cubic feet and 1.4 billion cubic feet, respectively, are the same as the totals at the bottom of the columns in table 6. Total volume of oak growing stock on timberland was 288.2 million cubic feet, which was 20.7 percent of all hardwood volume and 19.9 percent of all growing-stock volume. Trees at least 19 inches in diameter constituted 39.4 percent of the net volume of hardwood growing stock.

The net volume of sawtimber on timberland was 5.3 billion board feet (table 8). As with many other measures of coverage and abundance in Kansas, hardwoods constituted the preponderance of the volume (97.1 percent or 5.1 billion board feet). Red and white oaks totaled 1.2 billion board feet or 22.6 percent of the hardwood volume. Trees 19 or more inches in diameter were 53 percent of the hardwood volume (2.7 billion board feet). In 1994, the 19+ inch diameter classes constituted 50.8 percent of the total hardwood volume (Leatherberry *et al.* 1999).

## Biomass

The live aboveground biomass on timberland in Kansas totaled 70.6 million dry tons (table 9). More than 5 percent of that total was in 1- to 5-inch trees, 49.4 percent was in growing-stock trees, and 45.4 percent was in non-growing-stock trees. Private landowners held 94.3 percent or 66.6 million tons; public landowners held 5.7 percent (4 million dry tons). Of the 34.9 million dry tons in growing-stock trees, 92.1 percent were on private land and 7.9 percent were on public land. Among non-growing-stock trees, 96.5 percent were on private land and 3.5 percent were on public land (fig. 7).

Close to 73 percent of the total biomass of growing-stock trees was in the boles, and the remaining 26.6 percent was in stumps, tops, and limbs. Approximately the same proportions existed for the 32.1 million dry tons of non-growing-stock trees: 72.5 percent was in bolewood and 27.5 percent was in stumps, tops, and limbs.

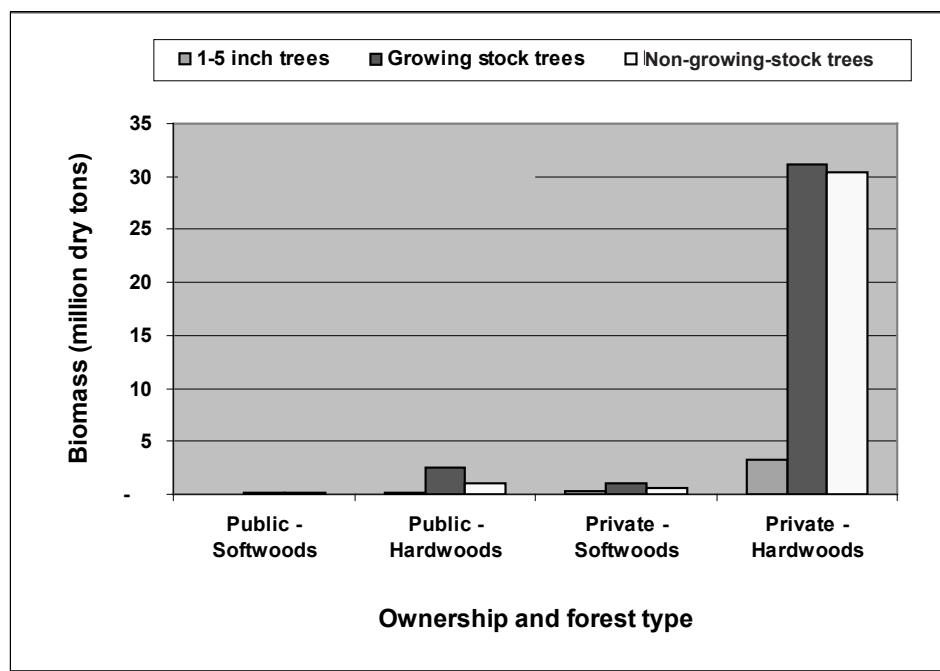

Figure 7.—Live aboveground biomass in Kansas, 2001-2004, in millions of dry tons, by ownership and forest type.

An interesting facet of these data is the relatively small proportion of aboveground biomass in non-growing-stock softwood trees (27.8 percent of all softwood biomass) versus non-growing-stock hardwood trees (46.5 percent of all hardwood biomass). These data suggest that a higher proportion of hardwood volume is made up of species of little or no commercial value and that hardwoods are more likely to have defects that result in low quality timber.

Further data related to the three most recent inventories of Kansas (2001, 2002 and 2003) are available at: [www.ncrs2.fs.fed.us/4801/fiadb/index.htm](http://www.ncrs2.fs.fed.us/4801/fiadb/index.htm).

## APPENDIX

### Inventory Methods

Since the 1998 inventory of Kansas, several changes have been made in NCFIA inventory methods to improve the quality of the inventory as well as to meet increasing demands for timely forest resource information. The most significant difference between inventories was the change from periodic to annual inventories. Historically, NCFIA periodically inventoried each State on a cycle that averaged about 12 years. However, the need for timely and consistent data across large geographical regions, combined with national legislative mandates, resulted in NCFIA's implementation of an annual inventory system.

With the NCFIA annual inventory system, about one-fifth of all field plots is measured each year. This report includes information from plots measured in 2001, 2002, 2003, and 2004: four-fifths of the plots that will be measured. In 2005, the entire inventory cycle will be completed (all of the plots will have been measured) and NCFIA will report and analyze results as a moving 5-year average (2001-2005). With each additional year of plot measurements, a fifth of the plots will be remeasured and an updated report will be prepared. For example, the 2007 measurement will be used to prepare an updated report based on plots measured in 2003 through 2007.

Although there are great advantages with an annual inventory, one difficulty is reporting on results during the first 4 years. For the 2001-2004 annual panels, approximately 80 percent of all field plots have been measured. Sampling error estimates for the 2004 inventory results are area of forest land, 4.72 percent; area of timberland, 4.90 percent; number of growing-stock trees on timberland, 7.56 percent; volume of growing stock on timberland, 9.32 percent; and volume of sawtimber on timberland, 11.41 percent. These sampling error estimates are higher than those for the last periodic inventory completed in 1994 (e.g., 1.59 percent for timberland area and 2.18 percent for growing-stock volume) because of the smaller samples. Thus, caution should be used when

drawing conclusions based on this limited data set. As we complete measurement of additional panels, we will have greater confidence in our results due to the increased number of field plots measured.

Other significant changes between our old and new inventory methodologies include new remote sensing technology, new sampling design and plot configuration, and the gathering of additional remotely sensed and field data. Advancements in remote sensing technology since the previous inventory in 1994 have allowed NCFIA to use classifications of Multi-Resolution Land Characterization (MRLC) data and other available remote sensing products to stratify the total area of the State and improve the precision of estimates.

New algorithms were used in 2001-2004 to assign forest type and stand-size class to each condition observed on a plot. These algorithms are being used nationwide by FIA to increase consistency among States and will be used to reassign the forest type and stand-size class of every plot measured in the 1994 inventory when it is updated. This will be done so that changes in forest type and stand-size class will more accurately reflect actual changes in the forest and not changes in how values are computed. The list of recognized forest types, grouping of these forest types for reporting purposes, models used to assign stocking values to individual trees, definition of nonstocked, and names given to the forest types changed with the new algorithms. As a result, comparisons between the published 2001-2004 inventory results and those published for the 1994 inventory may not be valid. For additional details about algorithms used in both inventories, please contact NCFIA.

### **Inventory Phases**

The 2004 Kansas survey was based on a three-phase inventory. The first phase used classified satellite imagery to stratify the state and aerial photographs to select plots for measurement. The second phase measured the traditional FIA suite of mensurational variables, and the third phase focused on a suite of variables related to the health of the forest.

The only land that could not be sampled was (1) private land where field personnel could not obtain permission from the owner to measure the field plot and (2) plots that could not be accessed because of a hazard or danger to field personnel. The methods used in the preparation of this report make the necessary adjustments to account for sites where access was denied or hazardous.

### **Phase 1**

The 2004 inventory used a classification of satellite imagery. FIA used the imagery to form two initial strata—forest and nonforest. Pixels within 60 m (2 pixel widths) of a forest/nonforest boundary formed two additional strata—forest edge and nonforest edge. Forest pixels within 60 m on the forest side of a forest/nonforest boundary were classified into a forest edge stratum. Pixels within 60 m of the boundary on the nonforest side were classified into a nonforest edge stratum. In addition, all strata were divided into public or private ownership based on information available in the Protected Lands Database (DellaSala *et al.* 2001). The estimated population total for a variable is the sum across all strata of the product of each stratum's area (from the pixel count) and the variable's mean per unit area (from plot measurements) for the stratum.

### **Phase 2**

Phase 2 of the inventory consisted of the measurement of 7,094 field plots in Kansas, 385 of which were found to contain forest land. Current FIA precision standards for annual inventories require a sampling intensity of one plot for approximately every 6,000 acres. FIA has divided the entire area of the United States into nonoverlapping hexagons, each of which contains 5,937 acres (McRoberts 1999). An array of field plots was created by establishing one plot within each hexagon (McRoberts 1999). This array of plots is designated the Federal base sample and is considered an equal probability sample; its measurement in Kansas is funded by the Federal government. No additional sample plots beyond the Federal base sample were taken in Kansas.

The total Federal base sample of plots was systematically divided into five interpenetrating, nonoverlapping subsamples or panels. Each year the plots in a single panel are measured, and panels are selected on a 5-year, rotating basis (McRoberts 1999). For estimation purposes, the measurement of each panel of plots may be considered an independent systematic sample of all land in a State. Field crews measure vegetation on plots currently classified as forest by trained photointerpreters using aerial photos or digital orthoquads.

### **Phase 3**

NCFIA has two categories of field plot measurements—phase 2 field plots (standard FIA plots) and phase 3 plots (forest health plots)—to optimize our ability to collect data when available for measurement. Both types of plots are systematically distributed both geographically and temporally. Phase 3 plots are measured with the full suite of forest health monitoring vegetative and health variables (Mangold 1998) collected as well as the full suite of measures associated with phase 2 plots. Phase 3 plots must be measured between June 1 and August 30 to accommodate the additional measurement of nonwoody understory vegetation, ground cover, soils, and other variables. The 2001-2004 annual inventory results represent field measures on 385 phase 2 forested plots and 29 phase 3 field plots.

The new national FIA plot configuration (fig. 8) was first used for data collection in Kansas in 2001, the first annual inventory year. This configuration will be used in subsequent years. The national plot configuration requires mapping forest conditions on each plot.

The estimation of change factors such as growth, mortality, and removals requires data from the remeasurement of plots, two measurements of the same plot taken several years apart. Because of the change to the national plot configuration, NCFIA will not have remeasurement information until the 2006 measurements. Until plot remeasurement data are available, we will be able to report

estimates of only the current state of the forest. The 2006 panel measurements will provide change observations on only one-fifth of our sample plots. Consequently, we will not report change estimates in Kansas until at least four annual panels have been remeasured in 2009. When the annual inventory has been completed in 2010, the full range of change data will be available.

The overall plot layout for the new configuration consists of four subplots. The centers of subplots 2, 3, and 4 are located 120 feet from the center of subplot 1. The azimuths to subplots 2, 3, and 4 are 0, 120, and 240 degrees, respectively. The center of the new plot is located at the same point as the center of the previous plot if a previous plot existed within the sample unit. Trees with a d.b.h. 5 inches and larger are measured on a 24-foot-radius (1/24 acre) circular subplot. All trees less than 5 inches d.b.h. are measured on a 6.8-foot-radius (1/300 acre) circular microplot located 12 feet east of the center of each of the four subplots. Forest conditions that occur on any of the four subplots are recorded. Factors that differentiate forest conditions are changes in forest type, stand-size class, land use, ownership, and density. Each condition that occurs anywhere on any of the subplots is identified, described, and mapped if the area of the condition meets or exceeds 1 acre in size.

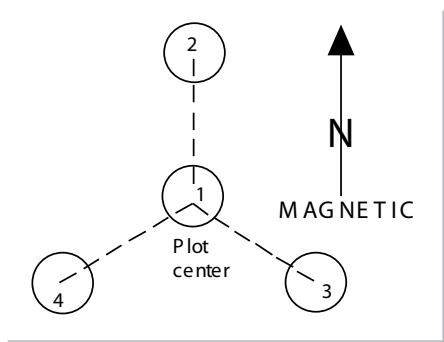

Figure 8.—Current NCFIA field plot design.

Field plot measurements are combined with phase 1 estimates in the compilation process and table production. The number of tables presented here is limited. However, other tabular data can be generated at: [www.ncrs2.fs.fed.us/4801/fiadb/index.htm](http://www.ncrs2.fs.fed.us/4801/fiadb/index.htm).

Moser, W. Keith; Hansen, Mark H.; Brand, Gary J.; Powers, Melissa.

2006. **Kansas' forest resources in 2004.** Resour. Bull. NC-259. St. Paul, MN: U.S. Department of Agriculture, Forest Service, North Central Research Station. 30 p.

This publication presents some of the major findings of the first 4 years of the fifth inventory of Kansas' forest resources. Since 1994, total forest land area has increased by more than 580,000 acres, to 2,126,100 acres. As with earlier inventories, oak/hickory is the largest forest type on the landscape, making up more than 52.3 percent of all forested land. Softwoods make up approximately 5.4 percent of Kansas' forested acreage. In 2001-2004, the net volume of all live trees and salvable dead trees on timberland was 2.73 billion cubic feet. The increases in forest land area and volume are due, in part, to a change in the definition of forest land, which has allowed lands formerly categorized as "non-forest" to be defined as "forest."

KEY WORDS: Annual inventory, forest area, forest type, volume, biomass, Kansas.

## **MISSION STATEMENT**

---

We believe the good life has its roots in clean air, sparkling water, rich soil, healthy economies and a diverse living landscape. Maintaining the good life for generations to come begins with everyday choices about natural resources. The North Central Research Station provides the knowledge and the tools to help people make informed choices. That's how the science we do enhances the quality of people's lives.
